

Twincretin and triple G drugs in management of diabetes

Alireza Esteghamati, MD

Professor of Endocrinology and Metabolism

Agenda

- Introduction
- Dual agonist structure
- Tirzepatide a promising drug studies
- Triple agonist in treatment of diabetes

Three decades ago

The (impossible?) Mission:

Discover a new class of drugs that safely reduce body weight by 20-30% to overcome obesity and prevent type 2 diabetes.

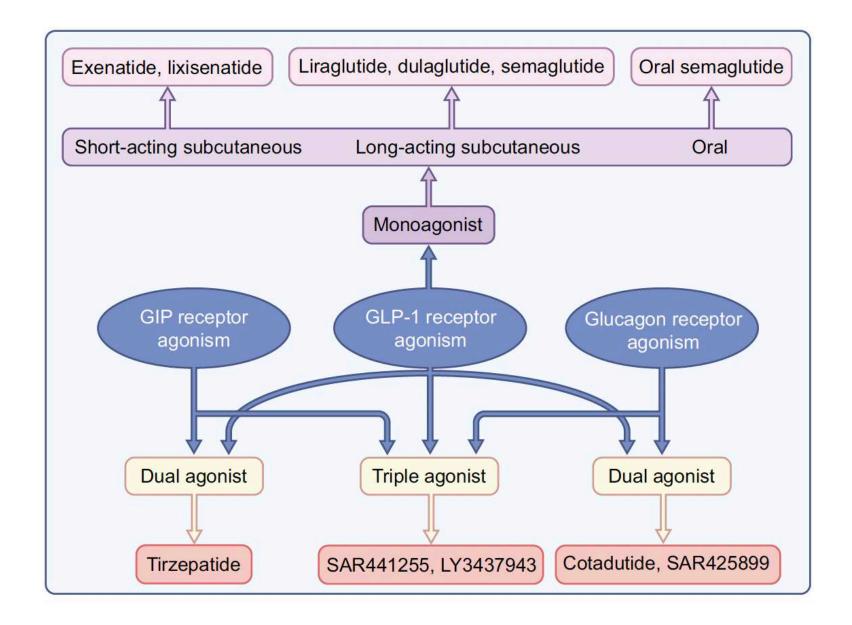

Munich University Hospital 1993

Introduction

- The diabetes pandemic is still here and still growing.
- The **twin epidemics** of obesity and type 2 DM will continue to pose major health challenges in coming decades.
- Despite numerous scientific advances bringing improvement to patients' life over last 100 years, since Banting discovered insulin, we have not managed to control, reverse or to prevent diabetes worldwide.
- RCTS of new IBT showed promising reductions in HbA1c and body weight and have been hailed as a game- changers in the diabesity community.

Schematic illustration of:

- Monoagonists
- Dual agonists
- Triple agonists
- Based on <u>GLP-1</u>, <u>GIP and</u> <u>glucagon</u> receptor activation alone or in combination

Twincretin

 Co- administration of GIP and GLP1 has an additive insulinotropic effect in healthy individuals and in those with T2DM2

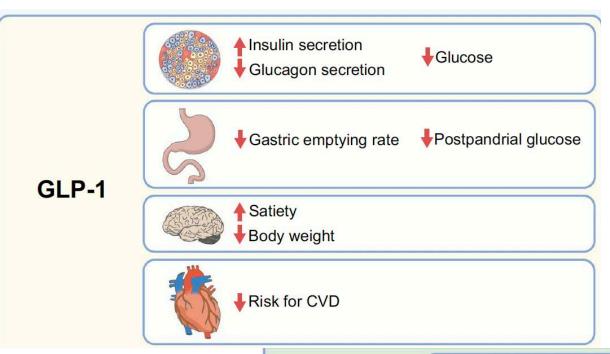

The first 'twincretin' was a **unimolar** dual agonist of GIP and GLP1 receptors, which induced:

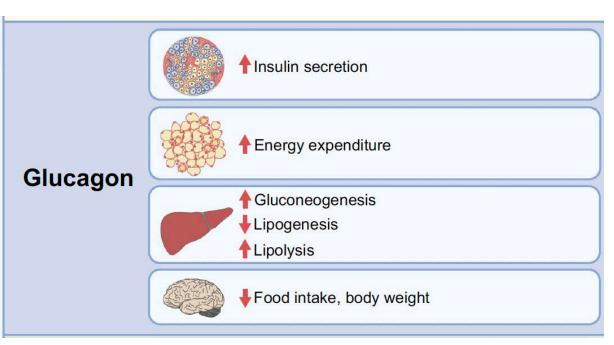

- 1. Superior dose- dependent weight loss
- 2. Reductions in blood glucose
- Reduced food intake

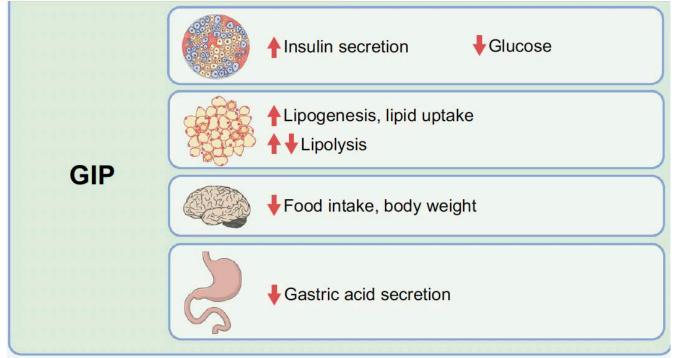

Single molecule dual agonist

- Initial studies adding a second incretin hormone, GIP, to GLP-1 receptor agonism <u>did not suggest any amplification</u> of the <u>metabolic effects</u>.
- Combining physiology, biology, chemistry, and pharmacology toward one common goal, discovering drugs that allows safe and effective drugs to control DM and obesity.
- However, the <u>development</u> of a single-molecule dual agonist, which binds to both the GLP-1 and GIP receptors, has had different outcomes.

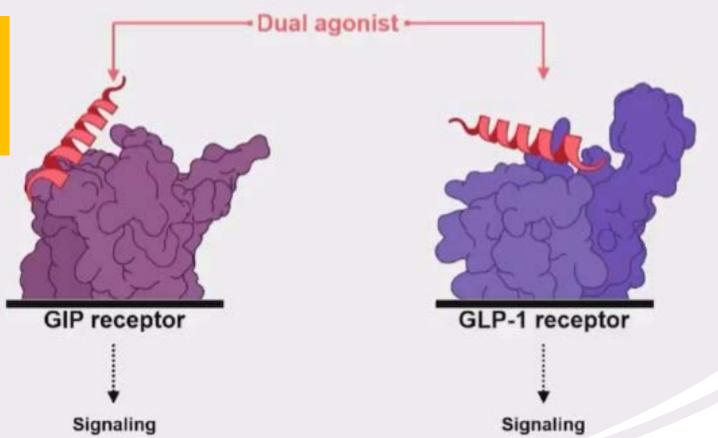

Discovery of a 2nd dual gut hormone receptor agonist for treatment of obesity and diabetes

Maximize beneficial effect on satiety, energy balance and glucose metabolism

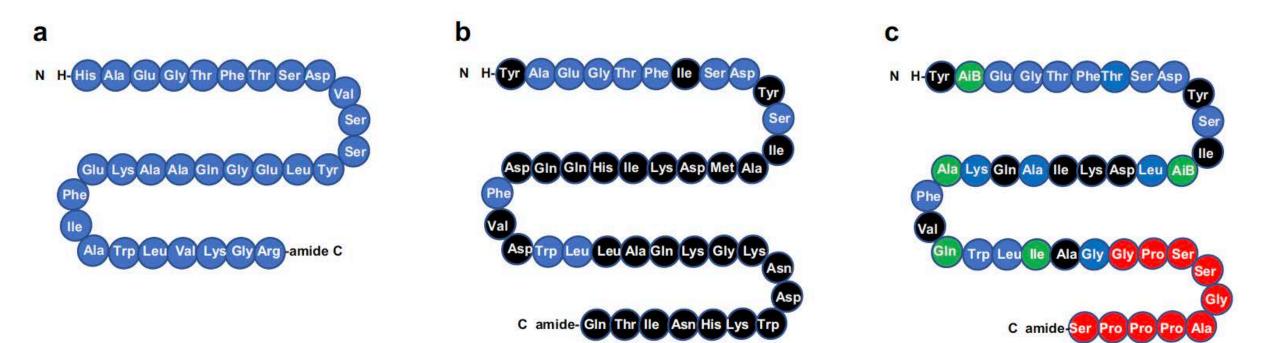

Activating multiple receptors

Tirzepatide is a synthetic linear peptide molecule containing 39 amino acids

Structures of (a) GLP-1, (b) GIP and (c) tirzepatide

In early 2016 Eli Lilly first applied a method of glycemic control using tirzepatide

Residues derive from GLP-1, GIP and semaglutide, and a few residues are unique

Green circles show amino acids that are present in tirzepatide but not in GLP-1, GIP or exenatide

Tirzepatide: A Promising Drug for T2DM and Beyond

 Tirzepatide is a promising drug with dual-acting GIP and GLP-1 receptor activation that has revolutionized the treatment of T2DM as an adjunct to diet and exercise.

It is conjugated to a C20 fatty diacid moiety which reversibly binds to albumin, prolonging its half-life to approximately 5 days, which allows for once-weekly subcutaneous dosing

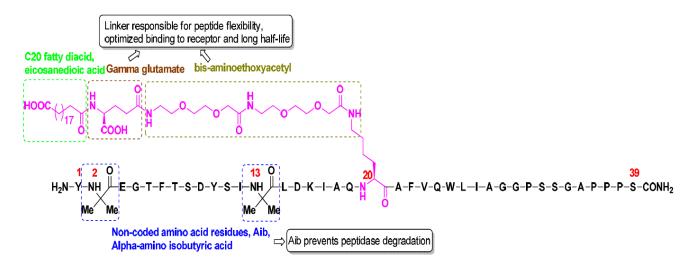

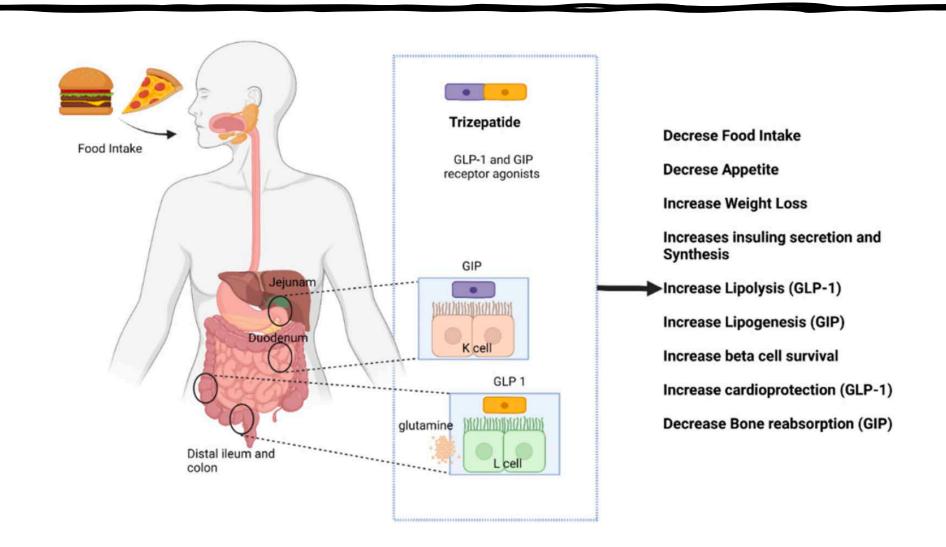

Figure 2. Structural features of tirzepatide, amino acids are denoted as single-letter codes.

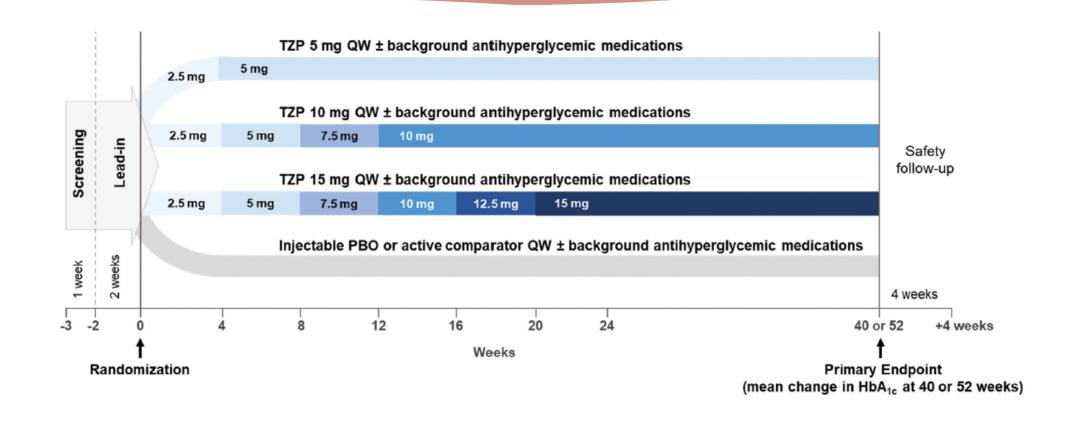

Mechanisms of action of tirzepatide within the human body

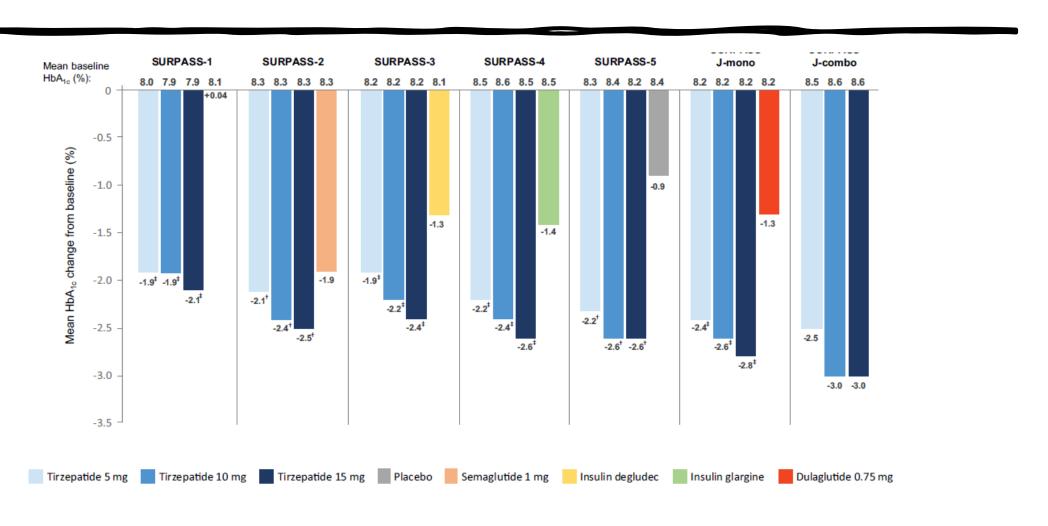

Tirzepatiden in SURPASS trials

| Study | comparator | |
|-----------------|--------------------------|------------------------|
| SURPASS-1 | placebo-controlled trial | |
| SURPASS-2 | semaglutide | |
| SURPASS-3 | insulin degludec | Metformin +/- SGLT2 -I |
| SURPASS-4 | Insulin glargine | High CVD Risk |
| SURPASS-5 | Insulin glargine | placebo |
| SURPASS-6 | Prandial insulin | |
| SURPASS-J mono | Dulaglutide | |
| SURPASS-J combo | OAD | |

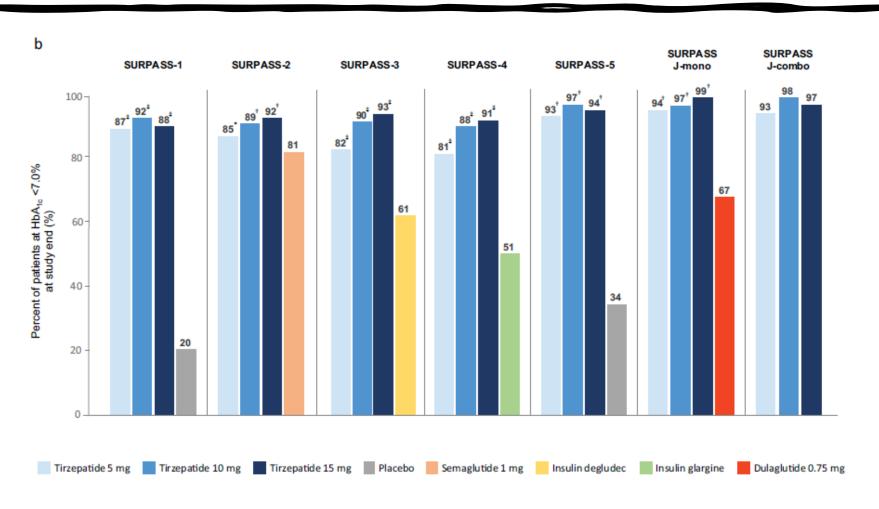

Study design and dose escalation of SURPASS trials

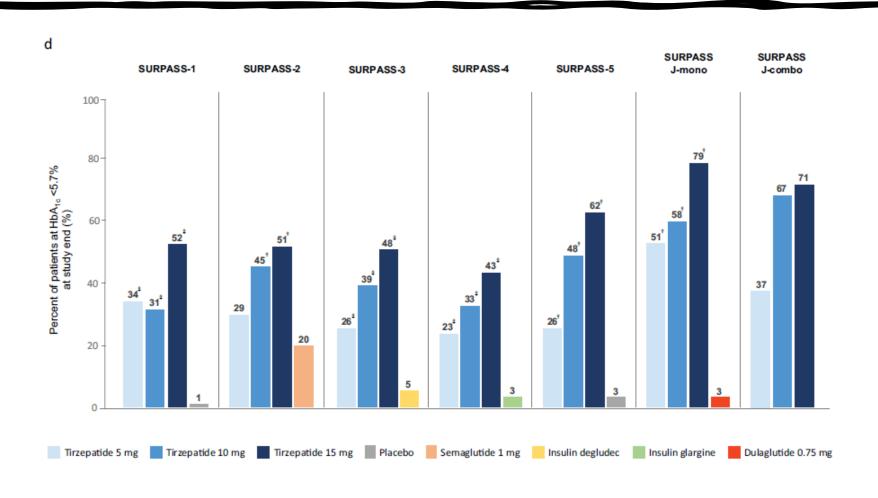

Change in HbA1c from baseline at study end

Proportion of patients achieving a HbA1c <7.0% at study end

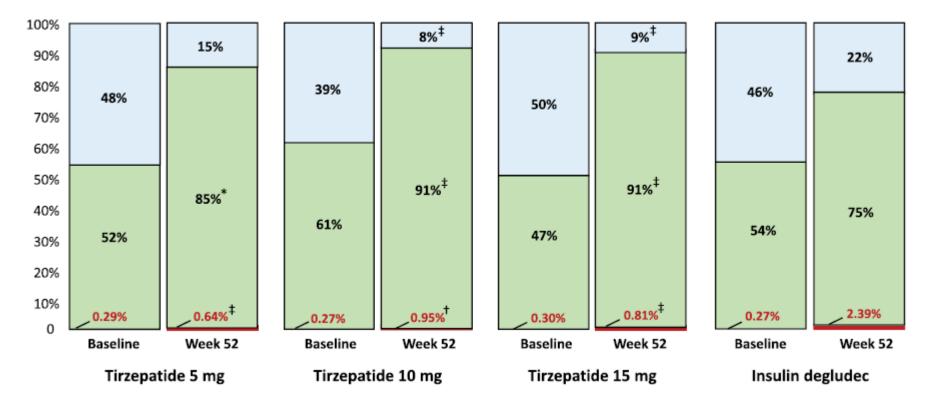

Proportion of patients achieving a HbA1c <5.7% at study end

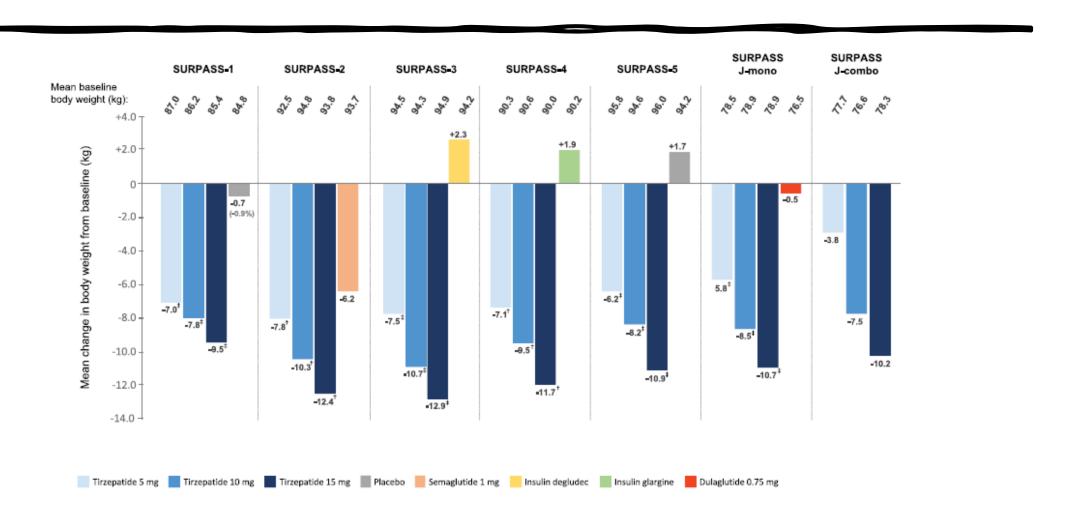

Proportion of TAR (>180), TIR (71–180), TBR (≤70) during a 24-hour period at baseline and week 52 for tirzepatide

The improvement in HbA₁₀ was due to reduction in both fasting/preprandial and postprandial glucose, as demonstrated by 7-point SMBG profiles and CGM

Change in body weight from baseline at study end

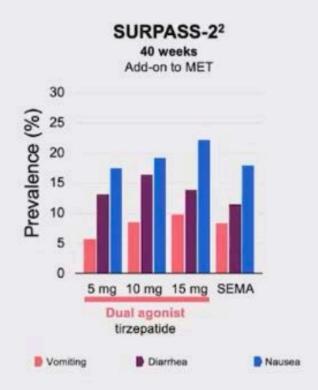

Most reported adverse events

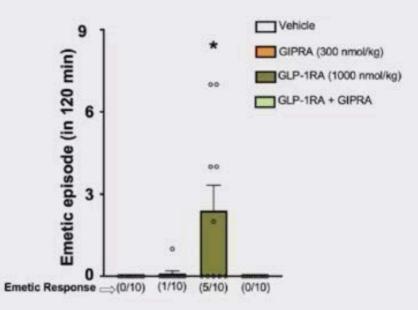

| | Nausea (%) | Diarrhea (%) | Vomiting (%) |
|------------|------------|--------------|--------------|
| SURPASS-1 | 12–18 | 12–14 | 2–6 |
| SURPASS-2 | 17–22 | 13–16 | 6–10 |
| SURPASS-3 | 12–24 | 15–17 | 6–10 |
| SURPASS-4 | 12–23 | 13–22 | 5–9 |
| SURPASS-5 | 13–18 | 12–21 | 7–13 |
| SURMOUNT-1 | 25–33 | 19–23 | 8–12 |

The GIP-GLP-1 receptor agonist tirzepatide: Superior efficacy without increasing side effects

GIP Receptor Agonism Attenuates GLP-1 Receptor Agonist-Induced Nausea and Emesis in Preclinical Models

Tirzepatide vs Insulin Lispro Added to Basal Insulin in Type 2 Diabetes

The SURPASS-6 Randomized Clinical Trial

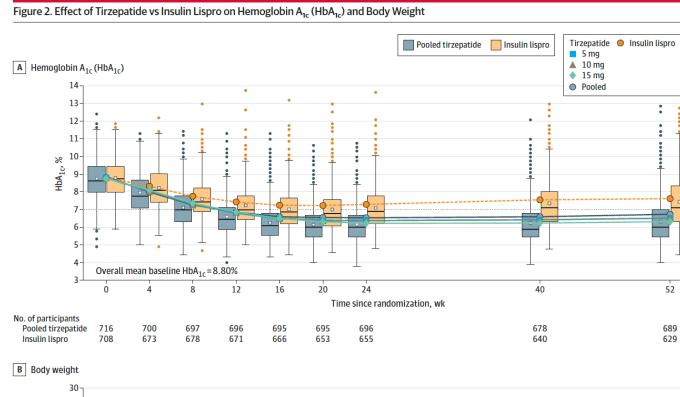

Julio Rosenstock, MD; Juan P. Frías, MD; Helena W. Rodbard, MD; Santiago Tofé, MD; Emmalee Sear Ruth Huh, PhD; Laura Fernández Landó, MD; Hiren Patel, MPharm

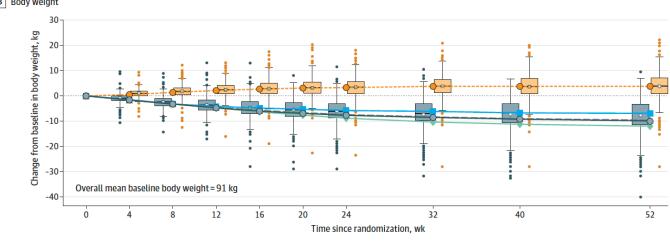

CONCLUSIONS AND RELEVANCE

In people with inadequately controlled T2DM treated with basal insulin

weekly tirzepatide compared with prandial insulin as an additional treatment with insulin glargine demonstrated:

Reductions in HbA1c and body weight with less hypoglycemia.

Retatrutide, a GIP, GLP-1 and glucagon receptor agonist, for people with type 2 diabetes: a randomised, double-blind, placebo and active-controlled, parallel-group, phase 2 trial conducted in the USA

meaningful improvements in glucose control and lipid metabolism, as well as robust bodyweight reductions via decreased energy intake and increased energy expenditure.

Julio Rosenstock, Juan Frias, Ania M Jastreboff, Yu Du, Jitong Lou, Sirel Gurbuz, Melissa K Thomas, Mark L Hartman, Axel Haupt, Zvonko Milicevic, Tamer Coskun

Added value of this study Retatrutide treatment

- significant and clinically meaningful improvements in glycemic control.
- Robust bodyweight reductions, did not plateaued by 36 weeks.
- Improved lipid profile and reduced BP, improved cardiometabolic outcomes.
- The safety profile was consistent with the GLP-1 RA and GIP and GLP-1 RA classes, with mild-to-moderate and transient GI adverse events, commonly reported.

Take home message

What are clinicians to make of these early results?

- The glucose-lowering effect of retatrutide is certainly substantial, but we now have large focus on weight management.
- Although the weight reduction of >16% with retatrutide at 36 weeks is impressive
- <u>active comparator was dulaglutide 1-5 mg</u>, which is not renowned for weight loss

Lower than the highest licensed weekly dose 4-5 mg

What are clinicians to make of these early results? challenges

• If glucagon agonism induces <u>increased</u> <u>energy expenditure</u>, a mechanism quite different to the satiety induced by GLP-1, then <u>long-term cardiovascular outcome</u> <u>trials will almost certainly be requested</u> by regulators, slowing the pathway to clinical use.

What are clinicians to make of these early results?

- phase 3 clinical trial programme of retatrutide to include comparisons with
- 1. <u>higher dose GLP-1 RA</u>
- 2. dual incretin agonists

is needed, and other triple agonists will continue to be developed.

• <u>Safety is always crucial</u> in the assessment of new therapies but, if confirmed, then the efficacy of glucose lowering, and weight reduction could prove to be valuable in the management of people with type 2 diabetes.

Take home message

 The discovery of triple receptor agonist drugs established yet another class of novel therapeutics which at least preclinically and it seems clinically may outperform mono and dual agonist as highly effective diabetes and obesity drugs.

 Of course, there are numerous other multireceptor drugs are now being tested, have the potential to transform the metabolic medicine.
